LA PLACE STRATÉGIQUE 17

Modeling examples using Geeglee

//

The theory is the practice!

An unknown, but clever, person

"

Modeling is not unique! Thus, all the following demonstrations can achieved in another way

Zone Controllers

architecture

TWO ZONE CONTROLLERS

THREE ZONE CONTROLLERS

FOUR ZONE CONTROLLERS

23/03/2023

INTRODUCTION

Modern car embedded more and more sensors/actuators (S&A) as well as intelligence to provide new function as ADAS, smart ambient light...

To provide function to driver, car's S&A must be connected together through Zone Controllers (ZC).

Example of Zone Controller architectures

INTRODUCTION

Modern car embedded more and more sensors/actuators (S&A) as well as intelligence to provide new function as ADAS, smart ambient light...

To provide function to driver, car's S&A must be connected together through Zone Controllers (ZC).

Engineers are looking to find the best architectures of ZC.

Example of Zone Controller architectures

INTRODUCTION: FIRST STEP FOR LATER...

Sensors are characterized by:

- Their position in car (fixe one),
- Their type and number of I/O,
- The supply they need to work (supply is provided by ZC),
- The computation power to achieve the function (complexity of algorithm)

Each zone controller is defined by:

- Its PCB surface,
- Its volume,
- Its configuration,
- Its weight,
- Its cost

INTRODUCTION

Each zone controller must be fit into one of the installation space constraints by the vehicle level.

One ZC per installation space.

It's NOT mandatory to fill all installation space with ZC.

Problem Settings: The black box view

Pattern it to Geeglee!

CREATE THE GEEGLEE PATTERN

Geeglee's model must cover the connexion of all S&A to a ZC allocated into installation space (and insure it must fit in).

More over, due to car's configuration, some sensors might not needed. Project management is looking to a robust architecture.

Cluster definition

FIRST APPROACH

The problem can solved by a clustering approach.

Each S&A will be allocated to a cluster and then Geeglee will be used to find the best allocation of cluster to zone controller.

The advantage of this approach is to avoid a large combination to test that can be irrelevant (as, for instance, to set two sensors, physically close, to a front and a rear ZC – so far away ZCs).

In this objective, Geeglee model owner must set the smallest size he want to analyse. In this example, we propose four (left representation beside) but it should be much more to refine quality of exploration (including asymmetrical ones).

Example of clusters definition

Cluster definition

SECOND APPROACH

The problem can solved by testing all allocation of S&A to any potential ZC.

It's the same principle of allocating cluster to ZC but using directly S&A to ZC.

The disadvantage of this approach is to test a very large combination some that could be for sure, irrelevant. But for sure, sometimes counterintuitive solutions can be a breakthrough!

For the rest of this exercise, the first approach, using clusters, have been selected

Example of clusters definition

Step 0: Set your project & SOI

- Nothing special here, create:
 - A SOI: « ZC architecture » for instance (but it work also if you choose another name),
 - An architecture: « ref. » for instance,
 - A first module: « M1 » for now,
 - A first alternative: « A1 » for « M1 »

Step 1: Set sensors list to Environment systems

BLACK BOX

- As you are not the person in charge of the selection of sensors & actuators embedded into the car, it's, for you, an environment systems
 - For our example, four has been listed here but you must list (or import) all the potential car S&A!

•••		v2.6.x		■ ⊕ ☐ ⊗ ⊕ ↓ ↓ ⊖ □ ≥ ◄ ⊕

Step 2: Set characteristics to describe sensors

- Sensors can be characterized by their number of I/O per cluster (thus their location are implicite to the cluster). To explain that to the software, characteristics « Cx (# I/O) » has been created.
 - X =[1..n], n the number of cluster
- A perspective should be to set all type of I/O per cluster

Step 3: Set values for environment alternatives (1/2)

- Define the number of I/O for each sensor/actuator.
- *Remark that:*
 - ✓ a sensor can be shared between clusters,
 - ADAS is composed, in this case, of two sensors,
 - An alternative « No ADAS_X » has been created to set the case of no ADAS is installed in the car. These alternatives has been set with « 0 » values for each cluster.

Step 5: Set incompatibilities

- Due to market expectations some sensors must not be installed in a car together.
 - In our case, « Not market » means that nomarket exist for instance for a car using « Front & Back ambiant light » and « No ADAS_1 »
- Another constraint is due to the need to used only compatible type of ADAS: « Only one type »

Step 10: Set group to describe your logic

- A good practice while using groups is to set your logic of thinking:
 - What is the first step of analysis, the second...
- In our project:
 - « 00 Cluster I/O def. »
 - ~ « 01 #I/O per IS_ »
 - ✓ « 02- IS_area »
 - ✓ ...
 - The logic of each group is explain on the following slides.

Step 17: Set constraints to validate that zone controler volum is not over installation space volum

- « Requirement constraints » can be then set for each Installation Space.
- As Geeglee explore the full design space (all the possible allocation of I/O (thus ZC) into IS_) if, it's not fitting, it can be delete (unfaisible solution)

The Wind Farm

The Wind Farm PROJECT

OBJECTIVES

Creating the model of a wind farm in **Geeglee Pattern**

- Focus on:
 - · Power
 - Energy production
 - · Project's Economics

Choosing the best solution in **Geeglee Intelligence**

- · Creating a datapage to be able to choose
- · Playing a scenario to take a decision

Functional BreakDown (FBS) down to Product (PBS)

"

Some relevant data for the project

Field – Dimensions & Price

Field - Wind

Mean Wind Speed at 50m [m/s]

Wind Shear exponent [-]

Field - Data

	Streamwise dimension [m]	Spanwise dimension [m]	Per-hectare Price [€/ha]	Mean wind speed at 50 m [m/s]	Wind shear exponent [-]

M5000 (Multibrid)	116	102	5,444	0,0734	0,1689	4	25	5000	13

ARRAY Arrangement

Spacing:

Streamwise spacing ratio $(Sx)[-] = \{6; 9\}$ Spanwise spacing ratio $(Sy)[-] = \{4; 5; 6\}$

Number of turbines:

 $Number of rows - Spanwise [\#] = \begin{bmatrix} Spanwise dimension [m] - 2 * Rotor diameter [m] \\ Sy * Rotor diameter \\ Sy * Rotor diameter \\ \hline \\ Streamwise dimension [m] - 2 * Rotor diameter [m] \\ \hline \\ Sx * Rotor diameter \end{bmatrix}$

Number of Wind Turbines [#] = Number of rows – Streamwise [#]* Number of rows – Spanwise [#]

Wind Speed at Hub height [m/s]

Wind distribution At Hub height

Distribution of wind speed at hub height approximated using Rayleigh distribution

One parameter: σ

 σ determined using mean wind speed at hub height:

$$\sigma = \overline{U}_{hub} * \sqrt{\frac{2}{\pi}}$$

Rayleigh distribution – Probability density function

Wind distribution – Obtaining Representative Wind Speed values

Obtention of representative wind speed values, using the cumulative distribution function

$$CDF(x) = 1 - e^{-\frac{x^2}{2\sigma^2}}$$
 with $x \ge 0$

Therefore:

$$CFD^{-1}(y) = \sigma \sqrt{-2 * \ln(1-y)}$$
 with $y \in [0; 1[$

10th decile 9th decile 0.8 8th decile 7th decile 0.6 6th decile 5th decile 0.4 4th decile 3rd decile 0.2 2nd decile 1st decile 2 8 10 6 0 4

Rayleigh distribution – Cumulative distribution function

Mean Power Computation – Single Turbine

Wind Power is given by the following formula:

$$P(u) = \begin{cases} 0, & u < u_{cut-in} \\ P_r * \frac{u^3 - u_{cut-in}^3}{u_{rated}^3 - u_{cut-in}^3}, & u \le u_{rated} \\ P_r, & u \le u_{cut-out} \\ 0, & u \ge u_{cut-out} \end{cases}$$

Mean Wind Power for one turbine:

$$\overline{P_1} = \frac{1}{10} \sum_{i=1}^{10} P(u_{i-th \ decile})$$

Mean Power Computation – Array

Mean Power Computation – SOME KPI

KPIS RELATED TO POWER & ENERGY:

- Total Installed Power [kW]
- ✓ Total Mean Power [kW]
- Capacity factor [%]
- Power density [kW/ha]
- Field yearly energy production [kWh]

Economics of the project

KPIS RELATED TO ECONOMIC ANALYSIS OF THE PROJECT:

- ✓ CAPEX [M€]
- ✓ Yearly OPEX [M€/y]
- ✓ Yearly Revenue [M€/y] (function of Electricity Price [€/kWh])
- ✓ Yearly Depreciations [M€] (function of Operations duration [y])
- ✓ Yearly Free Cash Flows during Operations [M€]: (function of Tax rate [%])

 $FCF = (1 - \tau) * (Revenue - OPEX) + \tau * Depreciations, where \tau is the tax rate$

Annuity Present Value Factor [-]: (function of Discount rate [%])

 $APVF = \frac{(1+r)^{operations\ duration} - 1}{r*(1+r)^{operations\ duration+construction\ duration}}$

✓ NPV [M€]:

$$NPV = -CAPEX + APVF * FCF$$

Model perspectives

PERSPECTIVES TO ENRICH THE MODEL:

- Schedule of the Wind Turbines construction
- Improving CAPEX and OPEX estimation
 - Wind Turbines transportation
 - Distance to construction plants
 - Connection to grid
 - ✓ ...
- Off-shore Architecture
- Variable selling price
- Site accessibility limitations
- Project Portfolio
